In R (almost) everything is a vector

Atomic Vectors

Atomic Vectors

R has six atomic vector types, we can check the type of any object in R using the typeof() function

typeof()	mode()
logical	logical
double	numeric
integer	numeric
character	character
complex	complex
raw	raw

Mode is a higher level abstraction, we will discuss this in detail a bit later. There are additional types in R, e.g. generic vectors have type <code>list</code>, but more on these later. See <code>?typeof</code> for more information.

logical - boolean values (TRUE and FALSE)

[1] FALSE

```
typeof(TRUE)

## [1] "logical"

typeof(FALSE)

## [1] "logical"

## [1] "logical"

## [1] "logical"
```

R will let you use T and F as shortcuts to TRUE and FALSE is it a bad idea to use these as they are global variables that can be overwritter.

```
T ## [1] TRUE

T = FALSE

T
```

character - text strings

Either single or double quotes are fine, opening and closing quote must match.

```
typeof("hello")

## [1] "character"

typeof('world')

## [1] "character"

## [1] "character"

## [1] "character"
```

Quote characters can be included by escaping or using a non-matching quote.

```
"abc'123"

## [1] "abc'123"

'abc"123'
```

#Տtլսdio են syntax highlighting is helpful here to indicate where it thinks a string begins and ends.

Numeric types

double - floating point values (default numerical type)

```
typeof(1.33)

## [1] "double"

typeof(7)

## [1] "double"

## [1] "numeric"

## [1] "numeric"
```

integer - integer values (literals are indicated with an L suffix)

```
typeof( 7L )

## [1] "integer"

## [1] "numeric"

typeof( 1:3 )

## [1] "integer"

## [1] "numeric"

6 / 3
```

Concatenation

Atomic vectors can be grown (combined) using the concatenate c() function.

```
c(1, 2, 3)
## [1] 1 2 3
 c("Hello", "World!")
## [1] "Hello" "World!"
 c(1, 1:10)
 c(1,c(2, c(3)))
## [1] 1 2 3
```

Inspecting types

- typeof(x) returns a character vector (length 1) of the type of object x.
- mode(x) returns a character vector (length 1) of the mode of object x.

```
typeof(1)
                                                          mode(1)
                                                         ## [1] "numeric"
## [1] "double"
 typeof(1L)
                                                          mode(1L)
## [1] "integer"
                                                         ## [1] "numeric"
 typeof("A")
                                                          mode("A")
## [1] "character"
                                                         ## [1] "character"
 typeof(TRUE)
                                                          mode(TRUE)
## [1] "logical"
                                                         ## [1] "logical"
```

Type Predicates

- is.logical(x) returns TRUE if x has type logical.
- is.character(x) returns TRUE if x has type character.
- is.double(x) returns TRUE if x has type double.
- is.integer(x) returns TRUE if x has type integer.
- is.numeric(x) returns TRUE if x has mode numeric.

```
is.integer(1)
                                      is.double(1)
                                                                          is.numeric(1)
## [1] FALSE
                                     ## [1] TRUE
                                                                         ## [1] TRUE
                                                                          is.numeric(1L)
 is.integer(1L)
                                      is.double(1L)
## [1] TRUE
                                     ## [1] FALSE
                                                                         ## [1] TRUE
is.integer(3:7)
                                      is.double(3:8)
                                                                          is.numeric(3:7)
## [1] TRUE
                                     ## [1] FALSE
                                                                         ## [1] TRUE
```

Other useful predicates

- is.atomic(x) returns TRUE if x is an atomic vector.
- is.list(x) returns TRUE if x is a list.
- is.vector(x) returns TRUE if x is either an atomic vector or list.

```
is.atomic(c(1,2,3))

## [1] TRUE

## [1] FALSE

is.list(c(1,2,3))

## [1] FALSE

## [1] TRUE

## [1] TRUE

is.vector(c(1,2,3))

## [1] TRUE

## [1] TRUE

## [1] TRUE
```

Type Coercion

R is a dynamically typed language -- it will automatically convert between most types without raising warnings or errors. Keep in mind the rule that atomic vectors must always contain values of the same type.

```
c(1, "Hello")

## [1] "1" "Hello"

c(FALSE, 3L)

## [1] 0 3

c(1.2, 3L)

## [1] 1.2 3.0
```

Operator coercion

Operators and functions will also attempt to coerce values to an appropriate type for the given operation

```
log(1)
 3.1+1L
## [1] 4.1
                                                         ## [1] 0
 5 + FALSE
                                                          log(TRUE)
## [1] 5
                                                         ## [1] 0
 TRUE & FALSE
                                                          TRUE | FALSE
## [1] FALSE
                                                         ## [1] TRUE
 TRUE & 7
                                                          FALSE | !5
## [1] TRUE
                                                         ## [1] FALSE
```

Explicit Coercion

Most of the is functions we just saw have an as variant which can be used for explicit coercion.

```
as.logical(5.2)
## [1] TRUE

as.character(TRUE)
## [1] "TRUE"

as.integer(pi)
## [1] 3
```

```
as.numeric(FALSE)

## [1] 0

as.double("7.2")

## [1] 7.2

as.double("one")

## Warning: NAs introduced by coercion
## [1] NA
```

Conditionals & Control Flow

Logical (boolean) operators

Operator	Operation	Vectorized?
x y	or	Yes
x & y	and	Yes
!x	not	Yes
x y	or	No
x && y	and	No
xor(x, y)	exclusive or	Yes

Vectorized?

```
x = c(TRUE, FALSE, TRUE)
y = c(FALSE, TRUE, TRUE)

x | y

## [1] TRUE TRUE TRUE

x & y

## [1] FALSE FALSE TRUE

## [1] FALSE
## [1] FALSE
```

Note both $|\cdot|$ and && only use the first value in the vector, all other values are ignored, there is no warning about the ignored values.

Vectorization and math

Almost all of the basic mathematical operations (and many other functions) in R are vectorized.

```
c(1, 2, 3) + c(3, 2, 1) log(c(1, 3, ## [1] 4 4 4 ## [1] 0.0000
c(1, 2, 3) / c(3, 2, 1) sin(c(1, 2, ## [1] 0.3333333 1.00000000 ## [1] 0.8414
```

```
log(c(1, 3, 0))

## [1] 0.000000 1.098612 -Inf

sin(c(1, 2, 3))

## [1] 0.8414710 0.9092974 0.1411200
```

Length coercion

```
x = c(TRUE, FALSE, TRUE)
 v = c(TRUE)
 z = c(FALSE, TRUE)
x | y
                                                        y Z
## [1] TRUE TRUE TRUE
                                                       ## [1] TRUE TRUE
 x & y
                                                        y & z
## [1] TRUE FALSE TRUE
                                                       ## [1] FALSE TRUE
 x | z
## Warning in x | z: longer object length is not a multiple of shorter object
## length
## [1] TRUE TRUE TRUE
```

Length coercion and math

The same length coercion rules apply for most basic mathematical operators as well

```
x = c(1, 2, 3)
y = c(5, 4)
z = 10L

x + x

log(x)

## [1] 2 4 6

## [1] 0.0000000 0.6931472 1.0986123

x + z

## [1] 11 12 13

## [1] 0.5 0.4
```

```
x %% y
```

Warning in x%%y: longer object length is not a multiple of shorter object length
[1] 1 2 3

Comparison operators

Operator	Comparison	Vectorized?
x < y	less than	Yes
x > y	greater than	Yes
x <= y	less than or equal to	Yes
x >= y	greater than or equal to	Yes
x != y	not equal to	Yes
x == y	equal to	Yes
x %in% y	contains	Yes (over x)

Comparisons

```
x = c("A", "B", "C")
z = c("A")
x == z
                                                       x %in% z
## [1] TRUE FALSE FALSE
                                                      ## [1] TRUE FALSE FALSE
x != z
                                                       z %in% x
## [1] FALSE TRUE TRUE
                                                      ## [1] TRUE
x > z
## [1] FALSE TRUE TRUE
```

Conditional Control Flow

Conditional execution of code blocks is achieved via if statements.

```
x = c(1, 3)
if (3 %in% x)
   print("Contains 3!")
## [1] "Contains 3!"
if (1 %in% x)
   print("Contains 1!")
## [1] "Contains 1!"
if (5 %in% x)
   print("Contains 5!")
if (5 %in% x) {
   print("Contains 5!")
} else {
   print("Does not contain 5!")
```

if is not vectorized

```
x = c(1, 3)
 if(x == 1)
   print("x is 1!")
## Warning in if (x == 1) print("x is 1!"): the condition has length > 1 and only
## the first element will be used
## [1] "x is 1!"
 if (x == 3)
   print("x is 3!")
## Warning in if (x == 3) print("x is 3!"): the condition has length > 1 and only
## the first element will be used
```

Collapsing logical vectors

There are a couple of helper functions for collapsing a logical vector down to a single value: any, all

```
x = c(3,4,1)

x >= 2

## [1] TRUE TRUE FALSE

## [1] TRUE TRUE TRUE

any(x >= 2)

## [1] TRUE

any(x <= 4)

## [1] TRUE

any(x <= 4)
```

[1] TRUE

[1] FALSE

else if and else

```
x = 3

if (x < 0) {
    "x is negative"
} else if (x > 0) {
    "x is positive"
} else {
    "x is zero"
}
```

[1] "x is positive"

```
x = 0

if (x < 0) {
    "x is negative"
} else if (x > 0) {
    "x is positive"
} else {
    "x is zero"
}
```

[1] "x is zero"

if **and** return

If R conditional statements can return a value, the two following implementations are equivalent.

```
x = 5

s = if (x %% 2 == 0) {
    x / 2
} else {
    3*x + 1
}
```

```
## [1] 16
```

```
x = 5

if (x %% 2 == 0) {
   s = x / 2
} else {
   s = 3*x + 1
}
```

```
## [1] 16
```

Error Checking

stop and stopifnot

Often we want to validate user input or function arguments - if our assumptions are not met then we often want to report the error and stop execution.

```
ok = FALSE

if (!ok)
    stop("Things are not ok.")

## Error in eval(expr, envir, enclos): Things are not ok.

stopifnot(ok)

## Error: ok is not TRUE
```

Note - an error (like the one generated by stop) will prevent an RMarkdown document from compiling unless error = TRUE is set for that code chunk

Style choices

Do stuff:

```
if (condition_one) {
    ##
    ## Do stuff
    ##
} else if (condition_two) {
    ##
    ## Do other stuff
    ##
} else if (condition_error) {
    stop("Condition error occured")
}
```

Do stuff (better):

```
# Do stuff better
if (condition_error) {
   stop("Condition error occured")
}

if (condition_one) {
   ##
   ## Do stuff
   ##
} else if (condition_two) {
   ##
   ## Do other stuff
   ##
}
```

Exercise 3

Write a set of conditional(s) that satisfies the following requirements,

- If x is greater than 3 and y is less than or equal to 3 then print "Hello world!"
- Otherwise if x is greater than 3 print "!dlrow olleH"
- If x is less than or equal to 3 then print "Something else ..."
- Stop execution if x is odd and y is even and report an error, don't print any of the text strings above.

Test out your code by trying various values of x and y.
